# Home:

Project to design a spacecraft with a sail pushed by laser for traveling to Alpha Centauri

#### Variables

- different laser wattages
- solar sail materials/gemoetries/shapes
- beyond solar system
- ...

starter p5 code is live now on mike's lasersail github account instead of google to hold our documents, links, models, etc...

## ====== GUI:

Thoughts about what users see; how they understand and control what is going on.

How many of (DJR's) 6 basic drawings can we use for GUI? {first 3 are raw data) (

- Who/What=portrait;
- hoWmuch=chart; Where=map;
- When=timeline;
- How=flowchart/cause&effect (mechanism?);
- Why=summary/story/equation/deduction & prediction (/original causality?))

#### ======= Interactions:

- 1. Beam width
- 2. Material variables (strength, reflectiveness, specific heat)
- 3. Size of solar sail (area)
- 4. Shape of solar sail (angled as a corner reflector or otherwise)
- 5. Laser variables (Intensity, frequency, angle of divergence)
- 6. Time that laser is fired
- 7. Mass of whole craft

======= laser-data:

"If you project a typical two-millimeter-diameter laser beam 400 kilometers, or 240 miles (the altitude of Space Station), the resultant

beam diameter is about 1 kilometer. ... the intensity of the laser beam falls in proportion to its cross-sectional area. In this case, an initial beam of 2 millimeters expanded to 1 kilometer, reducing the intensity by a factor of about 250 billion."

- [] Centauri-dreams.org says "Greg Matloff recently proposed use of Graphene as a material for solar sails\*. With an areal density of a fraction of a gram and high thermal resistance, this material would be truly disruptive. Currently existing materials have a much higher areal density; a number crucial for measuring the performance of solar sails." {\*Matloff, G. L. (2012). Graphene, the Ultimate Interstellar Solar Sail Material? Journal of the British Interplanetary Society, 65, 378-381.}
